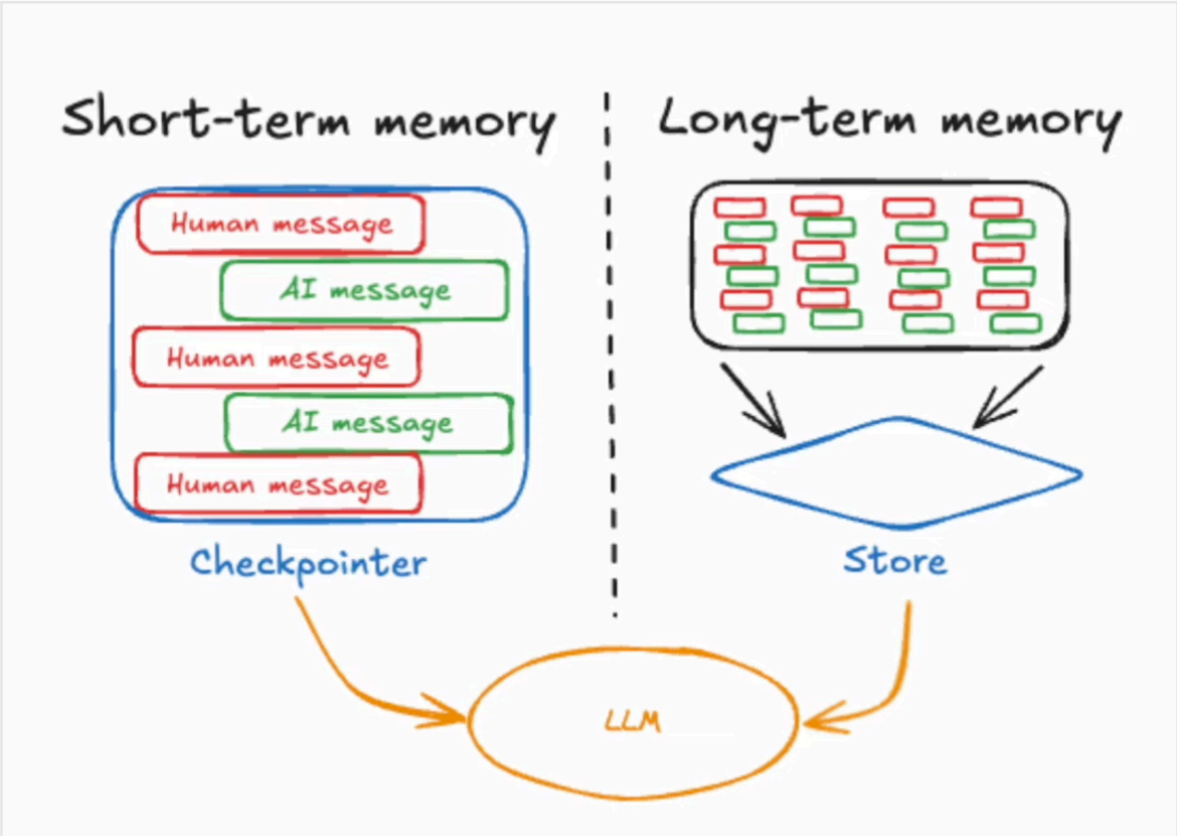
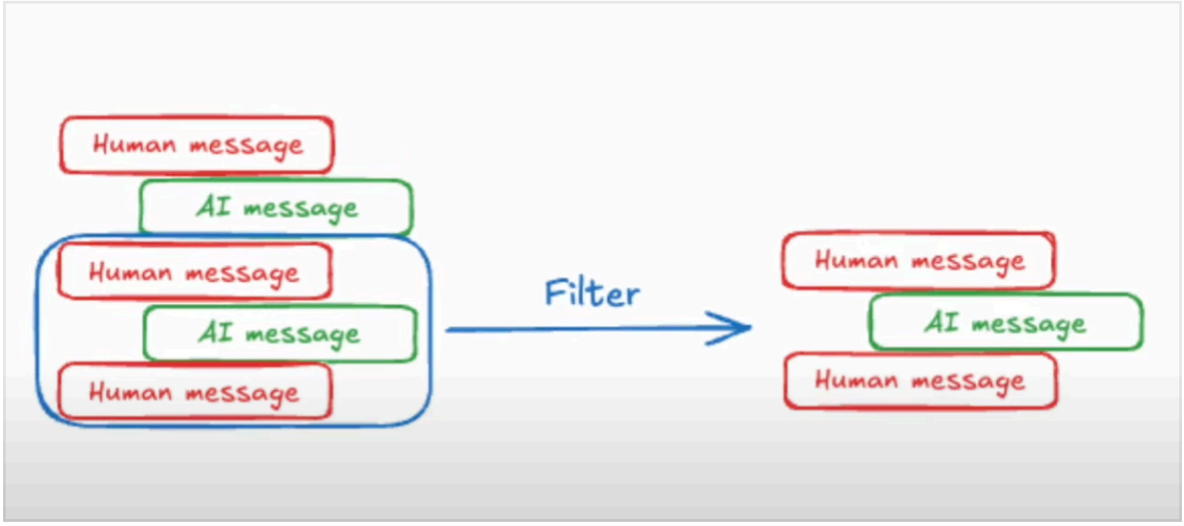
How does memory work in AI chat bots

Note: English is not good, images are

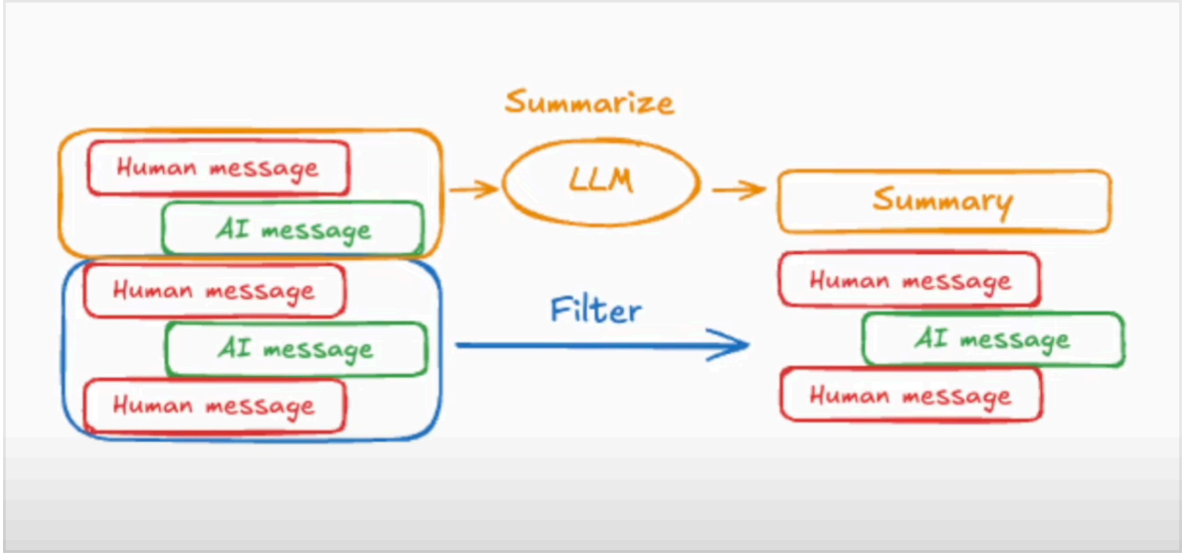


Short term memory = conservational memory (for specific threads)
Long term memory = store in langchain, used for across threads (new concept)

Short term memory

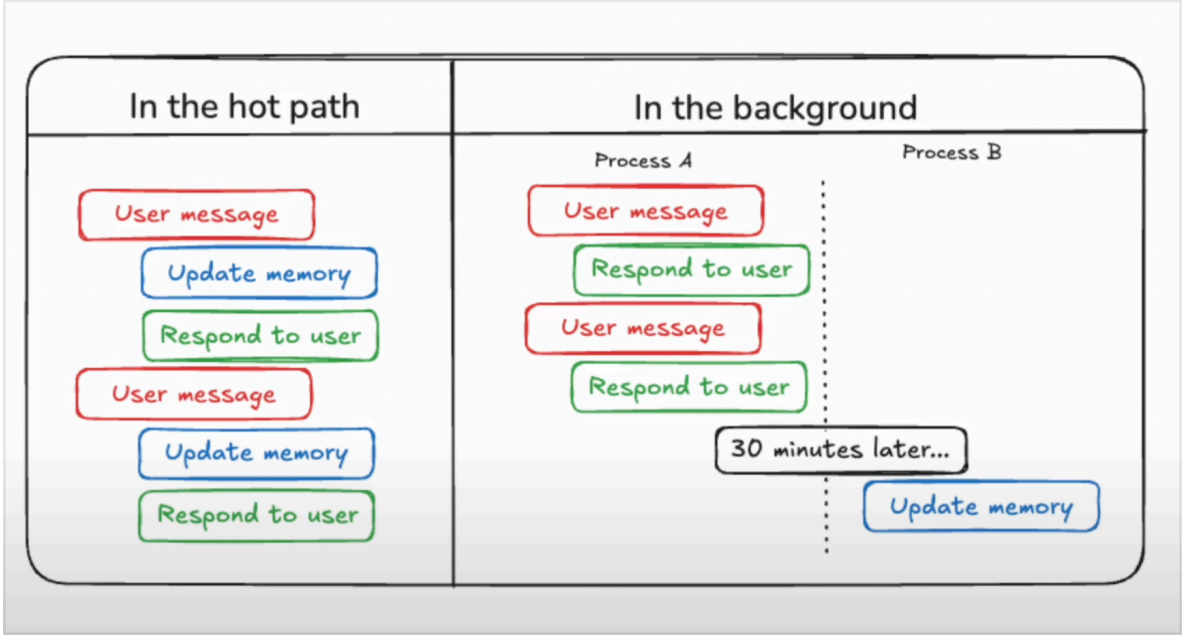


Filtering messages, keeping the last 10 messages, keeping human and AI messages rather than tools messages



Maybe to get more refinement we can have a summariser in llms to summarise the old

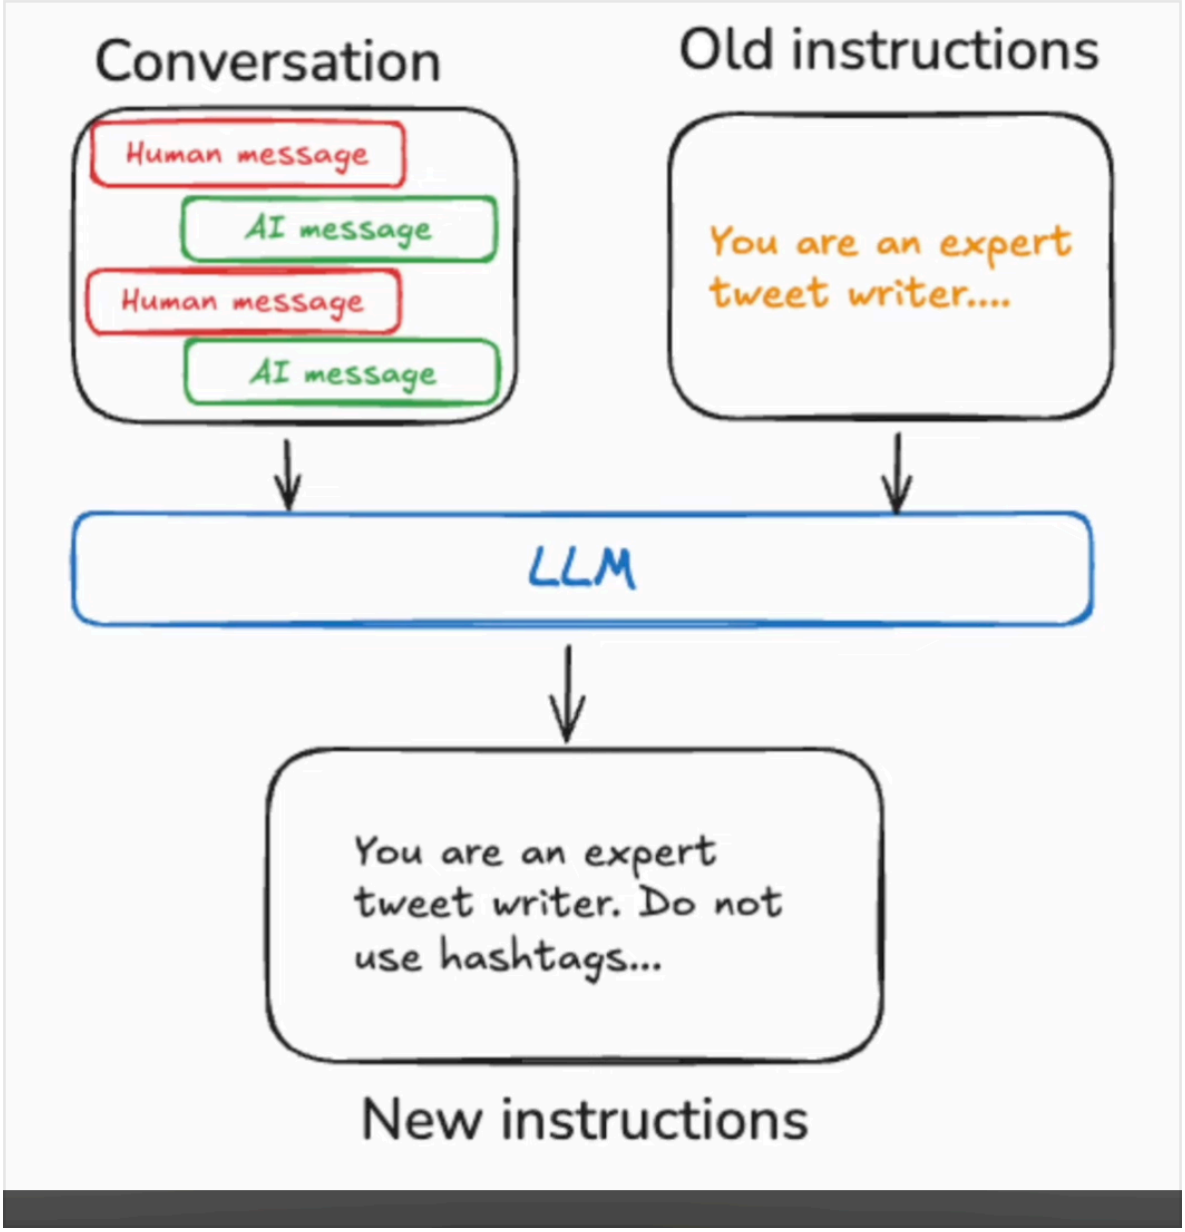
Long Term Memory



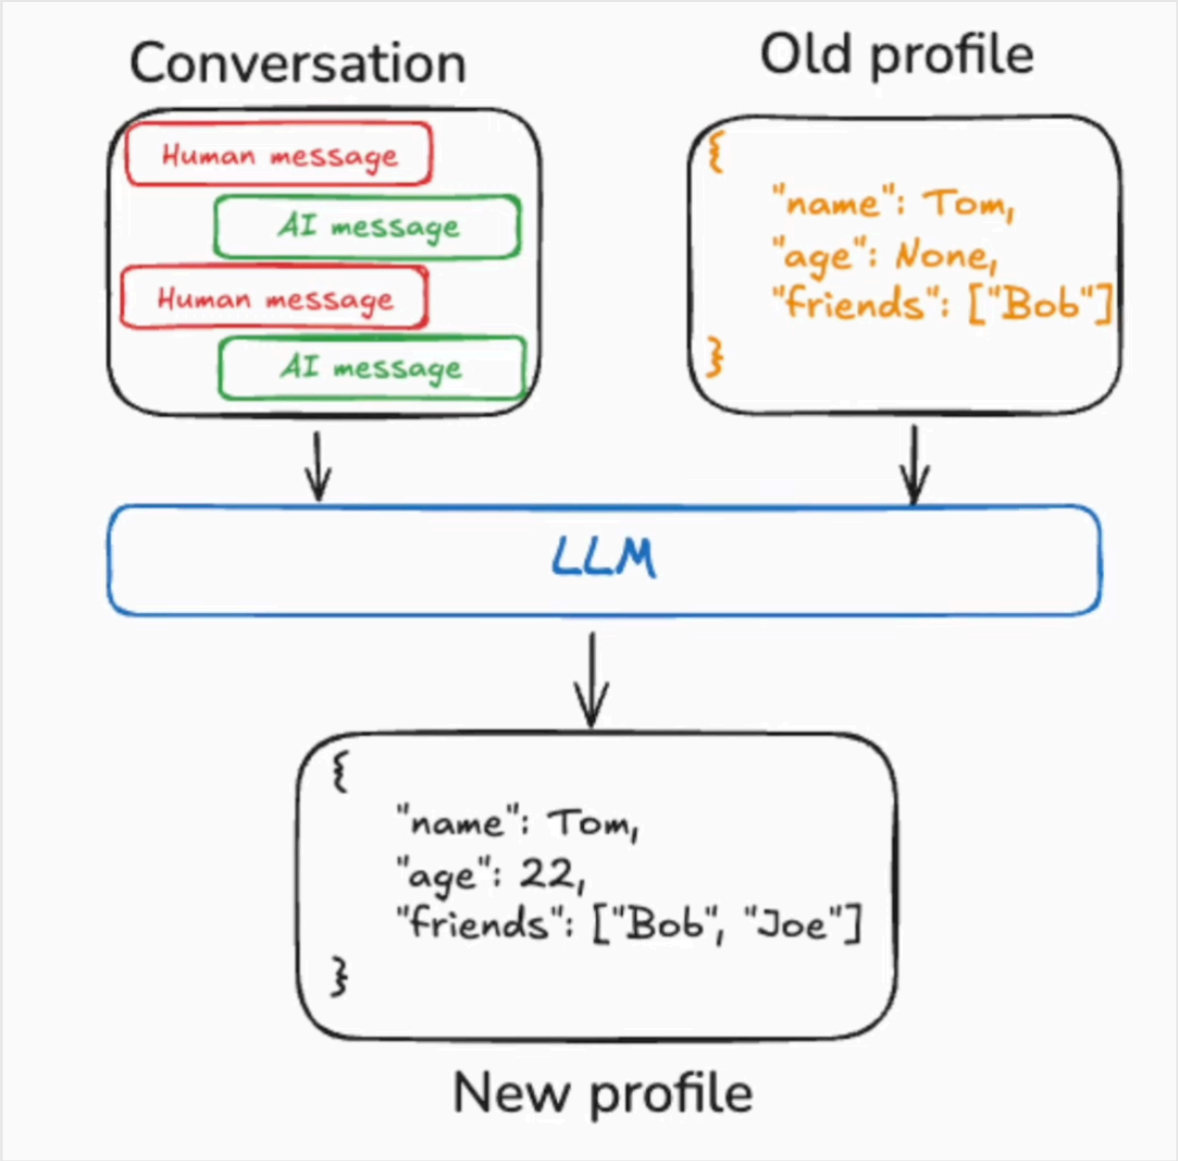
Two types of way to store long term memory

1. **Hot Path:** something like chatgpt, memory is loaded instantly, if user opens a new tab it will be visible that memory is loaded, but can be complicated
2. **In background:** you can pretty much understand it

Ways To Store Memory



If we combine our old system prompts instructions and conservations we will release that user is trying to always modify some of our prompts, so with the help of AI we can actually. Let them modify the system prompts for this



Usually memory is kind of string but if we make it as a profile then we can easily do it
A step above of this is
